**XYLOGLUCAN FUCOSYLTRANSFERASES****FIELD OF THE INVENTION**

This invention is in the field of molecular biology. In particular, this invention relates to the isolation, purification, cloning and expression of plant xyloglucan fucosyltransferases.

This application claims priority from US provisional serial no. 60/117,555 filed January 18, 1999 and US application serial no. 09/490,521 filed January 25, 2000.

**BACKGROUND OF THE INVENTION**

In most multicellular organisms, cells are embedded in an intricate extracellular matrix that keeps them together and influences the shape, development, and polarity of the cells they contact. Animal cells have such an extracellular matrix at their surface, but plants possess a distinct wall that encloses every cell. Many important differences between plants and animals with respect to nutrition, digestion, growth, reproduction, and defense mechanisms can be traced to the plant cell wall. Cell walls are mediators of growth, which in plants is determined largely by the wall extensibility provided that sufficient turgor pressure is present. Morphogenesis is also effected by the cell wall at the tissue and cellular levels. The biosynthesis of plant cell walls must be very tightly regulated. Although an individual plant cell may expand its volume by as much as 18,840 times, its cell wall must maintain a regular thickness and uniform structure to prevent hemorrhaging of the cell contents due to the high internal turgor pressure. However, despite extensive descriptions of the chemical and physical structure of the plant cell wall, very little is known about its biosynthesis. Only one cell wall-synthesizing glycosyltransferase, cellulose synthase, has been cloned and described in any detail

Plant cell walls are mainly composed of cellulose microfibrils and matrix polysaccharides. Hemicellulose is a type of matrix polysaccharide that binds tightly but noncovalently to cellulose microfibrils, helping to crosslink them into a complex network. Xyloglucan is a fundamentally important hemicellulose in dicot and nongraminaceous monocot plants. It comprises approximately 25% of the total cell wall and forms a load-bearing network by associating with the faces of surrounding cellulose microfibrils via hydrogen bonds. Xyloglucan contains a beta-1,4-glucan backbone decorated with side chains of xylose alone, xylose and galactose, and xylose, galactose and fucose. The presence or absence of the

fucose residue is thought to determine whether the xyloglucan conformation is planar and thus better able to bind to cellulose, a critical step in cell wall formation. In addition, oligosaccharides consisting of a monomer of xyloglucan have been shown to prevent auxin-promoted elongation of pea stems when the

5 oligosaccharides contain fucose, but not if they lack fucose suggesting that xyloglucan fragments act as signalling molecules in vivo. Xyloglucan fucosylation is thus a critical step in plant development.

There is thus a need to identify the genes and gene products involved in plant xyloglucan fucosylation. In particular, there is a need to isolate, purify and

10 clone xyloglucan fucosyltransferase genes and gene products so that xyloglucan fucosylation may be controlled and regulated in plants and other organisms.

### SUMMARY OF THE INVENTION

In order to meet these needs, the present invention is directed to purified,

15 isolated, sequenced and cloned plant xyloglucan fucosyltransferase. In addition, the present invention is directed to the purification, isolation, sequencing and cloning of plant xyloglucan fucosyltransferase. The present invention is further directed to transgenic organisms expressing plant xyloglucan fucosyltransferase. The present invention is further directed to transgenic plants expressing regulated

20 levels of xyloglucan fucosyltransferases.

*Sub B1* In general, the invention features substantially pure fucosyltransferase DNA or protein obtained from a plant. In a related aspect, the invention features a fragment or analog polypeptide including an amino acid sequence substantially identical to the sequences shown in Tables 2, 5 and 6.

25 *Sub B2* In another related aspect, the invention features substantially pure DNA having a sequence substantially identical to the nucleotide sequence shown in Tables 3-14. In preferred embodiments, such DNA is cDNA or is genomic DNA. In related aspects, the invention also features a vector and a cell (e.g., a plant) which includes such substantially pure DNA. In various preferred embodiments,

30 the vector-containing cell is a prokaryotic cell, for example, E. coli or Agrobacterium or, more preferably, a plant cell.

*Sub B3* In yet another related aspect, the invention features a method of fucosylating a polypeptide in vivo involving: (a) providing a cell containing the fucosyl transferase DNA of the invention positioned for expression in the cell; and

35 (b) culturing the transformed cell under conditions for expressing the DNA, resulting in the fucosylation of the protein. In preferred embodiments,

fucosylation occurs in a plant cell.

*Sub B4* →

In another aspect, the invention features a recombinant polypeptide fucosylated using a cell expressing DNA which is substantially identical to the nucleotide sequence shown in Tables 3-14. In still other preferred embodiments, the polypeptide is further fucosylated using one or more fucosyl transferases.

*Sub B5* →

The present invention further includes multiple types of DNA constructs including (1) "sense" constructs encoding proteins, which can increase the expression of fucosyltransferases in plant species and (2) "antisense" constructs containing DNA, which can be used to produce antisense RNA in to reduce expression of fucosyltransferases in plants. Optimal amounts of antisense RNA in transgenic plants will selectively inhibit the expression of genes in these plants which are involved in the fucosylation of xyloglucans.

Some of these constructs will direct constitutive production of transcripts. Other constructs will direct expression in specific organs and/or specific tissue layers of the transgenic plant. These organs will include leaves, petioles, stems, flower organs, seeds, fruits or photosynthetically active parts of the plant. Tissue layers will include but may not be restricted to the epidermis and adjacent cell layers.

The present invention also provides recombinant cells and plants containing these constructs.

*Sub B6* →

In one embodiment, the first category of DNA constructs include: a promoter selected from but not limited to constitutive, tissue-specific, cell-type specific, seed-specific, flower-specific, fruit-specific, epidermis-specific promoters, a promoter specific to cell layers adjacent to the epidermis or a promoter specific to photosynthetically active plant tissues, which functions in plant cells to cause the production of an RNA sequence. In this embodiment, the DNA coding region sequences that encode proteins which can be used to increase the activity of plant fucosyl transferases in transgenic plants. The DNA coding region will further include a region 3' to the coding regions the 3' non-translated region which functions in plant cells to cause the addition of polyadenylate nucleotides to the 3' end of the RNA sequence promoter.

*Sub B7* →

In another embodiment, a second category of DNA construct will include a constitutive promoter, seed-specific, flower-specific, fruit-specific, epidermis-specific promoter, a promoter specific to cell layers adjacent to the epidermis or a promoter specific to photosynthetically active plant tissues, which functions in plant cells to cause the production of an RNA sequence. The DNA construct will

also include DNA sequences which can produce antisense RNA molecules. These RNA molecules can selectively inhibit the accumulation of transcripts encoding proteins which encode plant fucosyl transferases.

5 *Sub B8* In accordance with another aspect of the present invention, there is provided a method of producing genetically transformed plants which express a gene or genes involved in fucosyl transferase activity. In this method, a recombinant, double-stranded DNA molecule into the genome of a plant cell. In this embodiment, the DNA sequence will include a promoter which functions in plant cells to cause the production of an RNA sequence in flowers, seeds, fruit or  
10 other plant tissues. In addition, the sequence will include a DNA coding sequence encoding proteins involved in fucosyl transferase activity in plants. Alternatively, the sequence will be a template to the synthesis of antisense RNA inhibiting the development of these structures. The DNA sequence will also include a 3' non-translated region which functions in plant cells to cause the addition of  
15 polyadenylate nucleotides to the 3' end of the RNA sequences. The method also includes obtaining transformed plant cells and regenerating from the transformed plant cells genetically transformed plants. The transformed plant cells may be used to overproduce in cell culture the fucosylated xyloglucans.

The present invention is also directed to transgenic cells such as yeast,  
20 fungi, mammalian, and the like cells expressing the DNA sequences of this invention. The present invention is also directed to purified fucosylated xyloglucans isolated from the transgenic cells of the invention.

*Sub B9*

#### BRIEF DESCRIPTION OF THE DRAWINGS

25 This invention will be better understood by reference to the figures, in which:

**Figure 1** shows the biochemical purification of xyloglucan-specific fucosyltransferase from pea. Figure 1A shows a silver-stained SDS-PAGE gels showing protein profiles from carbonate-washed pea epicotyl extract, peak  
30 fractions from a GDP-agarose and size exclusion column, and the entire profile of all fractions from an anion exchange column. Figure 1B shows a xyloglucan-specific fucosyltransferase activity, in nKat (= nMoles of substrate incorporated into product per second), for each fraction of the anion exchange column eluate.

**Figure 2** shows confirmation of Arabidopsis fucosyltransferase (Ftase) activity. Figure 2A shows that Anti-AtFT1 polyclonal antibodies recognize an approximately 62 kDa polypeptide in solubilized membrane proteins of Arabidopsis, but not pea. Lane 1, antigen (50 ng); Lane 2, Arabidopsis (40 :l), Lane 3, pea (40 :l.) Left, Western blot. Right, Commassie staining of membrane showing protein profiles. Figure 2B shows that anti-FTase antibodies immunoprecipitate more XG-specific FTase activity than an equal volume of preimmune serum. Shown is FTase activity, in nanokats, of precipitated pellets that were subsequently subjected to FTase activity assays. This is an example similar to results seen in seven different replicates. Figure 2C shows that a full-length AtFTase which was expressed in a COS cell line shows XG-specific FTase activity. Activity in nKat is shown in the presence or absence of tamarind XG for untransformed Cos-7 cells, cells transformed with vector DNA (pCDNA3), cells transformed with vector containing AtFT1 (pCDNA-XGFT), or solubilized pea Golgi vesicles.

**Figure 3** shows a hydrophobicity plot of AtFT1.

**Figure 4** shows a diagram of plasmid pMEN020.

## DEFINITIONS

To ensure a complete understanding of the invention, the following definitions are provided:

**Xyloglucan:** . Xyloglucan is a hemicellulose carbohydrate present in dicot and nongraminaceous monocot plants comprising approximately 25% of the total cell wall and forming a load-bearing network by associating with the faces of surrounding cellulose microfibrils via hydrogen bonds. Xyloglucan contains a beta-1,4-glucan backbone decorated with side chains of xylose alone, xylose and galactose, and xylose, galactose and fucose.

*Sub B10* **Xyloglucan fucosyltransferase:** Xyloglucan fucosyltransferase (XG Ftase) is an enzyme that fucosylates xyloglucan by adding a fucose residue to xyloglucan.

**Transgenic Plants:** Transgenic plants are plants which contain DNA sequences which were introduced by transformation.

5       **Promoter:** A promoter is the minimal DNA sequence sufficient to direct transcription. Promoters can render transcription controllable for cell-type specific, tissue-specific, or inducible expression. Promoter elements may be located in the 5' or 3' regions of the native gene.

10       **Poly-A Addition Site:** A poly-A addition site is a nucleotide sequence which causes certain enzymes to cleave mRNA at a specific site and to add a sequence of adenylic acid residues to the 3'-end of the mRNA.

15       **Polypeptide:** Polypeptide means any chain of amino acids, regardless of length or post-translational modification (e.g., glycosylation or phosphorylation).

20       **Substantially Identical:** For a polypeptide, substantially identical means a polypeptide exhibiting at least 50%, preferably 70%, more preferably 90%, and most preferably 95% identity to a reference polypeptide. For a nucleic acid substantially identical means a nucleic acid sequence exhibiting at least 85%, preferably 90%, more preferably 95%, and most preferably 97% identity to a reference nucleic acid sequence. For polypeptides, the length of comparison sequences will generally be at least 16 amino acids, preferably at least 20 amino acids, more preferably at least 25 amino acids, and most preferably 35 amino acids. For nucleic acids, the length of comparison sequences will generally be at least 30 nucleotides, preferably at least 60 nucleotides, more preferably at least 75 nucleotides, and most preferably 110 nucleotides.

30       Sequence identity is typically measured using sequence analysis software (e.g., Sequence Analysis Software Package of the Genetics Computer Group, University of Wisconsin Biotechnology Center, 1710 University Avenue, Madison, Wis. 53705). Such software matches similar sequences by assigning degrees of homology to various substitutions, deletions, substitutions, and other modifications. Conservative substitutions typically include substitutions within the following groups: glycine, alanine; valine, isoleucine, leucine; aspartic acid, glutamic acid, asparagine, glutamine; serine, threonine; lysine, arginine; and  
35       phenylalanine, tyrosine.

**Substantially Pur Polypeptid** : Substantially pure polypeptide means a fucosyltransferase polypeptide which has been separated from components which naturally accompany it. Typically, the polypeptide is substantially pure when it is at least 60%, by weight, free from the proteins and naturally-occurring organic molecules with which it is naturally associated. Preferably, the preparation is at least 75%, more preferably at least 90%, and most preferably at least 99%, by weight fucosyltransferase polypeptide. A substantially pure fucosyltransferase polypeptide may be obtained, for example, by extraction from a natural source (e.g., a plant) by expression of a recombinant nucleic acid encoding a fucosyltransferase polypeptide; or by chemically synthesizing the protein. Purity can be measured by any appropriate method, e.g., column chromatography, polyacrylamide gel electrophoresis, or HPLC analysis.

A protein is substantially free of naturally associated components when it is separated from those contaminants which accompany it in its natural state. Thus, a protein which is chemically synthesized or produced in a cellular system different from the cell from which it naturally originates will be substantially free from its naturally associated components. Accordingly, substantially pure polypeptides include, without limitation, those derived from eukaryotic organisms but synthesized in *E. coli* or other prokaryotes, or those derived from a eukaryotic cell which does not normally synthesize such a protein, or those derived from a eukaryotic cell engineered to overexpress such a protein.

**Substantially Pure DNA** : Substantially pure DNA means DNA that is free of the genes which, in the naturally-occurring genome of the organism from which the DNA of the invention is derived, flank the gene. The term therefore includes, for example, a recombinant DNA which is incorporated into a vector; into an autonomously replicating plasmid or virus; or into the genomic DNA of a prokaryote or eukaryote; or which exists as a separate molecule (e.g., a cDNA or a genomic or cDNA fragment produced by PCR or restriction endonuclease digestion) independent of other sequences. It also includes a recombinant DNA which is part of a hybrid gene encoding additional polypeptide sequence.

**Transformed Cell:** Transformed cell means a cell into which (or into an ancestor of which) has been introduced, by means of recombinant DNA techniques, a DNA molecule encoding (as used herein) a fucosyltransferase polypeptide.

**Positioned for Expression:** Positioned for expression means that the DNA molecule is positioned adjacent to a DNA sequence which directs transcription and translation of the sequence (i.e., facilitates the production of, e.g., a recombinant fucosyltransferase polypeptide or RNA molecule).

5

**Operably Linked:** Operably linked mean that a gene and a regulatory sequence(s) are connected in such a way as to permit gene expression when the appropriate molecules (e.g., transcriptional activator proteins) are bound to the regulatory sequence(s).

10

**Purified Antibody:** Purified antibody means an antibody which is at least 60%, by weight, free from proteins and naturally-occurring organic molecules with which it is naturally associated. Preferably, the preparation is at least 75%, more preferably 90%, and most preferably at least 99%, by weight, antibody, e.g., a plant fucosyltransferase specific antibody. A purified fucosyltransferase antibody may be obtained, for example, by affinity chromatography using recombinantly-produced fucosyltransferase protein or conserved motif peptides and standard techniques.

15

20

**Specifically Binds:** Specifically binds means an antibody which recognizes and binds fucosyltransferase protein but which does not substantially recognize and bind other molecules in a biological sample.

### DETAILED DESCRIPTION OF THE INVENTION

25

Taking into account these definitions, the present invention is directed to isolated, purified and cloned plant xyloglucan fucosyltransferases.

#### Plant Fucosyltransferase Purification

30

*Sub B11* → A biochemical approach was utilized to purify sufficient quantities of xyloglucan fucosyltransferases from pea epicotyls. Pea microsomes were prepared as follows: 2 cm segments, excised just below the apical hook, of etiolated *Pisum sativum*, cv Alaska were collected and homogenized in 1.5 volumes buffer (50 mM Hepes pH 7.5, 1 mM EDTA pH 8.0, 0.4 M sucrose, 1 mM DTT, 0.1 mM PMSF, 1 :g/mL each aprotinin, leupeptin, and pepstatin.) The homogenate was filtered, centrifuged at 2,000 x g for 15 minutes, and the supernatant was centrifuged at 100,000 x g for 1 hour. The resulting pellets were washed and homogenized in the presence of 0.1 M Na<sub>2</sub>CO<sub>3</sub> to strip away

35

peripheral membrane proteins (Y. Fujiki, A. L. Hubbard, S. Fowler, P. B. Lazarow, J. Cell Biol. 93, 97 (1982).) The suspension was centrifuged at 100,000 x g for 1 hour and the resulting pellets were washed and resuspended in buffer (50 mM Pipes-KOH pH 6.2, 20% glycerol, 1 mM EDTA, 1 mM DTT, 0.1 M PMSF, 1 :g/mL each aprotinin, leupeptin, and pepstatin.) The suspension was homogenized, mixed with TritonX-100 to a final volume of 0.8%, and stirred for 1-2 h to solubilize membrane proteins. The suspension was centrifuged a final time at 100,000 x g for 1 h and the supernatant was collected and saved.

Arabidopsis cell suspension culture was also used as a tissue source.

When Arabidopsis cell suspension culture was used, the purification procedure was the same except the cells were lysed in a French pressure cell at 4000 p.s.i.

Pea carbonate-washed supernatants were pooled and separated on a GDP-HA agarose affinity chromatography column and GDP-binding proteins were eluted using excess free GDP. Protein levels were monitored by A280. The protein samples were desalted on a Sephadex G-25 column, concentrated, and further separated on a Phenomenex SEC 4000 size exclusion column. Some samples were further purified using a Poros QE or Resource Q anion exchange column and subsequently column and separated by SDS-PAGE electrophoresis.

#### 20 **Fucosyl Transferase Assay**

A specific assay for fucosyl transferase was developed using tamarind or nasturtium storage xyloglucan, which naturally lack fucosyl residues, as an acceptor and radiolabeled GDP-fucose as a donor [V. Farkas, G. Maclachlan, *Arch. Biochem. Biophys.* **264**, 48 (1988). A. Camirand, D. Brummell, G. Maclachlan, *Plant Physiol.* **84**, 753 (1987)].

#### **Carbohydrate Analysis**

To confirm that the purified pea protein synthesizes an alpha-1,2 fucose:galactose linkage, carbohydrate analysis was performed on the product resulting from in vitro fucosylation of tamarind xyloglucan by purified FTase. Carbohydrate linkage analysis of tamarind xyloglucan before (tamarind xg) and after (fucosylated xg) incubation with purified pea FTase. Samples were incubated at room temperature for 20 minutes (for immunoprecipitation samples) or 30 minutes (for protein purification samples) with 25 mM Pipes-KOH pH 6.2, 0.5 mg/mL tamarind xyloglucan, 0.05% <sup>3</sup>H GDP-fucose (3.7 mBq/mL, 300 GBq/mM, NEN, Boston, MA). Most assays also contained 50 :M non-radiolabeled

GDP-fucose to provide a quantitative measurement of enzyme activity. Assays of immunoprecipitation samples also contained 5 mM MgCl<sub>2</sub>. Reactions were precipitated using 70% ethanol and <sup>3</sup>H incorporation was measured by scintillation counting. The amount of fucose incorporated into the product was used to calculate activity in nanokats (nKat = nMoles substrated incorporated into product per second.) The results are shown in Table 1.

Table I

Sugar Residue	% tamarind xg	% Fucosylated xg
4-glucose	16.4	17.5
4,6-glucose	37.0	31.5
t-xylose	19.0	13.5
2-xylose	15.0	14.3
t-galactose	12.6	5.5
2-galactose	-	9.0
t-fucose	-	8.7

10

Tamarind seed xyloglucan was fucosylated by 33 pKat size exclusion column-purified pea FTase (1 mg/mL tamarind XG, 1.5 mM GDP-fucose, 50 mM Pipes-KOH pH 6.2.) XG product was precipitated with ethanol, resuspended in water, reprecipitated, and sent to the Complex Carbohydrate Research Center (Athens, GA) for linkage analysis. An equal amount of tamarind xyloglucan was also submitted for linkage analysis. Linkage analysis indicated that incubation of XG with purified FTase resulted in a decrease in the mole percentage of terminal galactose and the appearance of 2-galactose and terminal fucose, thus verifying the activity of the purified enzyme.

20

### Peptide Sequencing

*Sub B15* It was possible to purify XG FTase 1400-fold by the end of the size exclusion chromatography step resulting in a total of 0.05 mg protein containing 70 nKat XG FTase activity. After biochemical purification and subsequent assay analysis, two polypeptides of approximately 65 kDa and 60 kDa in size were observed to co-purify repeatedly with XG FTase activity (Figure 1.)

25

*Sub B16* Limited peptide sequence was obtained from both proteins. Proteins in size exclusion column eluate fractions containing peak amounts of FTase activity were concentrated using a Millipore 4 mL 10 kDa concentrator and separated by electrophoresis. After brief staining with Coomassie and destaining the separated proteins were excised, rinsed in 50% acetonitrile, stored at -80° C and sent to

30

Harvard Microchemistry (Cambridge, MA) for tryptic peptide sequencing. Six peptide sequences were obtained: VFGFLGR, YLLHPTNNVWGLVVR, AVLITSLSSGYFEK, YYDAYLAK, LLGGLLADGFDEK, and ESILPDVNR.

5 *Sub B17* ~~Arabidopsis~~ **EST Identification**

*Sub B18* Using these peptides as a query in the Blastp program identified an Arabidopsis EST, 191A6T7, which contained four out of six peptides in a deduced translation of a potential ORF. The 65 kDa peptide was identified as a homolog of BiP, the usually ER-localized molecular chaperone. It is possible that this  
10 chaperone co-purified with FTase activity as an artifact and prevented the denaturation of the FTase during purification, though this has not been confirmed.

Peptides from the lower molecular weight protein were not significantly similar to proteins of known function in databases, but did allow the identification of an Arabidopsis EST which, when translated, contains four out of six peptides  
15 with amino acid identity ranging from 63%-85% (See Table 2).

The EST(number 191A6t7) was analyzed to determine if it was a full length clone. Northern blot analysis using the ~900 bp-long 191A6T7 as a probe detected an approximately 2 kb transcript, indicating that the EST did not contain the full-length cDNA (RMP, data not shown.).

20 191A6T7 was used as a probe to screen the CD4-15 portion of a size-fractionated Arabidopsis cDNA library at high stringency (J - J - Kieber, M. Rothenberg, G. Roman, K. A. Feldmann, J. R. Ecker, *Cell* **72**, 427 (1993). Two cDNA clones were isolated, the longest containing a 1768 bp insert. Both lacked 13 nucleotides of the 3' UTR and the poly-A tail found in 191A6T7. There  
25 is an AATAAA consensus polyadenylation signal eight nucleotides from the 3' end of the library-derived clones. The sequence contains a 1698 nucleotide ORF that encodes a 63.7 kDa protein a 1698 nt open reading frame (Table 3) and correspond to a region of the fully sequenced Arabidopsis bacterial artificial chromosome (BAC) T18E14 (Table 4).

30 The cDNA and corresponding genomic clone have been designated AtFT1. Interestingly, analysis of the BAC indicates that there may be a second FTase approximately 600 bp downstream from AtFT1 which is ~60% identical to AtFT1 (Table 5). Whether this second FTase is expressed, as well as splicing patterns and localization of the encoded protein, are matters of current  
35 investigation. It does raise the possibility that a multi-gene family of FTases may exist in Arabidopsis. We will determine whether members of such a family might

be differentially regulated by such factors as environmental stress, tissue localization, or developmental stage. Alternatively, there may well be FTases which have different acceptors, such as carbohydrate protein modifications.

## 5                    **Antibody Preparation**

In order to confirm the identity of AtFT1 as encoding a xyloglucan-specific fucosyltransferase, we prepared polyclonal antibodies directed against AtFT1 and used them to immunoprecipitate proteins from carbonate-washed, solubilized Arabidopsis proteins.

10                    *Sub B19*                    The portion of AtFT1 encoding aa 73 to 566 was PCR-amplified using appropriate primers and cloned into the pET28a expression vector (Novagen, Madison WI.) The resulting insoluble fusion protein was purified by washing four times with 1% Triton X-100, 50 mM Hepes-KOH pH 7.6, 10 mM MgCl<sub>2</sub> and one time with 25 mM Hepes-KOH pH 7.0, 8 M urea. The pellet was resuspended in 6  
15                    M guanidine-HCl and protein was precipitated from the supernatant with 10% TCA. The protein was emulsified with Titermax adjuvant (CytRx Corporation, Norcross, GA) and injected into a rabbit. For western blotting, 40 :l of carbonate-washed solubilized protein from pea and Arabidopsis and 50 ng of purified antigen were separated by SDS-PAGE and electroblotted. Anti-AtFT1  
20                    Abs (1:5000) were used for western blotting. Goat-antirabbit antibodies conjugated to horseradish peroxidase was used as a secondary antibody. Signals were detected by the enhanced chemiluminescence method (Pierce, Rockford, IL.) Membranes were then stained with Coomassie blue to detect protein.

## 25                    **Immunoprecipitations**

30                    *Sub B20*                    For immunoprecipitations, solid NaCl was added to carbonate-washed solubilized Arabidopsis protein to a final concentration of 200 mM. The Arabidopsis protein was precleared by incubation with 1/10 volume of 50% slurry of protein A sepharose beads (Pharmacia) in buffer A (25 mM Pipes-KOH pH 7.5, 50 mM NaCl, 2 mM EDTA pH 8.0.) The resulting supernatants were incubated  
35                    with 50 :l of immune or preimmune anti-AtFT1 serum for 1 h. 1/5 volume of protein A sepharose slurry was added to precipitate the antigen-antibody complexes and the samples were incubated for an additional 3 hours with rocking at 4 degrees C. Samples were then centrifuged, washed five times in buffer A containing 1% Triton X-100 and two times in buffer A without detergent. The pellets were

resuspended in buffer A to a final volume of 120 :l and assayed for AtFTase activity as described above.

Sub B21  
5 The immunoprecipitated proteins were then assayed for XG FTase activity. More FTase activity was correlated with pellets derived from immunoprecipitation reactions using immune antiserum rather than preimmune serum, thereby indicating that the Arabidopsis clone encodes a xyloglucan-specific FTase (Figure 2).

### Expression in COS Cells

Sub B22  
15 Cos-7 cells were grown on 100 mm plates in DMEM-10% Fetal Bovine Serum. Cells were transfected with different plasmids using Lipofectamine™ reagent (Life Technologies) following the manufacturer's instructions using 9 :g of DNA and 72 :g of Lipofectamine. Cells were incubated for 24 hours in the medium containing DNA-Lipofectamine without Fetal Bovine Serum. The medium was changed to DMEM-10% Fetal Bovine Serum and incubated for another 48 hours. The cells were scraped off the dish in 0.25 M sucrose, 10 mM Tris-HCl pH 7.5 and 0.4% CHAPS. XG-FTase activity was measured using 50 :g of protein in the absence (-XG) or presence (+XG) of 100 :g tamarind xyloglucan. The incubation was carried out in a volume of 0.1 mL in the presence of 1 :M GDP-Fuc; (93,000 dpm), 10 mM MnCl<sub>2</sub>, 20 mM Hepes pH 7.0, 0.05% Triton X-100 at 25°C for 90 min. The reaction was halted by adding ethanol to a final concentration of 70%. Samples were incubated at 4°C and filtered through 1.5 :m glass fiber filters. The filters were washed with 70% ethanol containing 1 mM EDTA. The filters were dried and radioactivity determined by liquid scintillation. A control using pea Golgi vesicles was carried out in parallel. The results indicate that AtFT1 expressed in a COS cell line showed in vitro FTase activity that was 41 times higher than COS cells transformed with an empty vector and 1.4 times higher than solubilized pea Golgi vesicles (Figure 2).

25  
30 Taken together, the in vitro translation data and the cos cell translation data provide strong evidence that AtFT1 is involved in xyloglucan biosynthesis.

### Sequence Analysis of AtFT1

Sub B23  
35 Analysis of AtFT1 indicates that, while it has some structural characteristics common to other fucosyltransferases, it is quite divergent at the amino acid sequence level. Hydrophobicity plots predict that there may be a

N-terminal transmembrane signal anchor sequence (see Figure 3). In vitro translation in the presence of canine pancreatic microsomes followed by carbonate washing of the products indicates that the AtFT1 translation product is a membrane protein (data not shown.) As with other glycosyltransferases, the C-terminal region is predicted to be largely hydrophilic.

AtFT1 is not significantly similar to any other FTases from other organisms, although multiple sequence alignments have identified three motifs which appear to be conserved among all alpha 1,2-FTases. One ([IV]G[IV]HQ)[VI]R..[DN]) has been described previously (Breton et al., 1998). In addition, a second motif (D[EK]..F.[EQ].DQ) and a third hydrophobic region was conserved.

Since these proteins have different acceptor molecules but share the same sugar nucleotide donor (GDP-fucose), it is possible that these regions are involved in GDP-fucose binding or that are necessary for assumption of conserved structural characteristics. Some small regions of similarity are observed between AtFT1 and NodZ, a fucosyltransferase in *Rhizobium* involved in the synthesis of nodulation factors.

#### Other Glycosyltransferases

The unique nature of this FTase allow its use as a tool for identifying other glycosyltransferases. Consideration of the number of different linkages present in plant cell wall polysaccharides indicates that there should be several hundred different glycosyltransferases involved in cell wall biosynthesis. Several other sequences in the Arabidopsis databases do appear to be similar to AtFT1 and AtFT2, and thus might represent a multi-gene family of FTases or glycosyltransferases. Substantially identical sequences are presented in Tables 6-14.

In addition to database analysis, the isolation of additional plant fucosyltransferases is made possible using standard molecular biology techniques. In particular, using all or a portion of the amino acid sequence of a plant fucosyltransferase of the invention, one may readily design fucosyltransferase oligonucleotide probes, including fucosyltransferase degenerate oligonucleotide probes (i.e., a mixture of all possible coding sequences for a given amino acid sequence). These oligonucleotides may be based upon the sequence of either strand of the DNA comprising the motif. General methods for designing and preparing such probes are provided, for example, in Ausubel et al., and Guide to Molecular Cloning Techniques, 1987, S.

L. Berger and A. R. Kimmel, eds., Academic Press, New York. These oligonucleotides are useful for fucosyltransferase gene isolation, either through their use as probes capable of hybridizing to fucosyltransferase complementary sequences or as primers for various polymerase chain reaction (PCR) cloning strategies. In one particular example, isolation of other fucosyltransferase genes is performed by PCR amplification techniques well known to those skilled in the art of molecular biology using oligonucleotide primers designed to amplify only sequences flanked by the oligonucleotides in genes having sequence identity to fucosyltransferase of the invention. The primers are optionally designed to allow cloning of the amplified product into a suitable vector.

Hybridization techniques and procedures are well known to those skilled in the art and are described, for example, in Ausubel et al. If desired, a combination of different oligonucleotide probes may be used for the screening of the recombinant DNA library. The oligonucleotides are labelled with <sup>32</sup>P using methods known in the art, and the detectably-labelled oligonucleotides are used to probe filter replicas from a recombinant DNA library. Recombinant DNA libraries may be prepared according to methods well known in the art, for example, as described in Ausubel et al., supra, or may be obtained from commercial sources.

For detection or isolation of closely related fucosyltransferases, high stringency conditions may be used; such conditions include hybridization at about 42 degrees C. and about 50% formamide; a first wash at about 65 degrees C., about 2X SSC, and 1% SDS; followed by a second wash at about 65 degrees C. and about 0.1% SDS, 1X SSC. Lower stringency conditions for detecting fucosyltransferase genes having about 85% sequence identity to the fucosyltransferase gene described herein include, for example, hybridization at about 42 degree C in the absence of formamide; a first wash at about 42 degrees C, about 6X SSC, and about 1% SDS; and a second wash at about 50 degrees C., about 6X SSC, and about 1% SDS.

Fucosyltransferase oligonucleotides may also be used as primers in PCR cloning strategies. Such PCR methods are well known in the art and described, for example, in PCR Technology, H. A. Erlich, ed., Stockton Press, London, 1989; PCR Protocols: A Guide to Methods and Applications, M. A. Innis, D. H. Gelfand, J. J. Sninsky, and T. J. White, eds., Academic Press, Inc., New York, 1990; and Ausubel et al., supra. If desired, fucosyltransferases may be isolated using the PCR "RACE " technique, or Rapid Amplification of cDNA Ends (see, e.g., Innis et al., supra). By this method, oligonucleotide primers based on a fucosyltransferase conserved domain are oriented in the 3' and 5' directions and are used to

generate overlapping PCR fragments. These overlapping 3'-and 5'-end RACE products are combined to produce an intact full-length cDNA. P.N.A.S. 85:8998(1988)

## 5 **Plant Transformation**

*Sub B2* Once identified, fucosyl transferase genes can be expressed in a variety of cells including plant cells, yeasts, fungi, bacterial cells and mammalian cells. A wide variety of plants can be transformed to express fucosyl transferase genes and genes related to fucosyl transferase in order to regulate plant carbohydrate glycosylation.

### **A. Dicots**

Methods for transforming a wide variety of different dicots and obtaining transgenic plants are well documented in the literature (See Gasser and Fraley 15 (1989) *Science* 244:1293; Fisk and Dandekar (1993) *Scientia Horticulturae* 55:5-36; Christou (1994) *Agro Food Industry Hi Tech* (March/April 1994) p.17, and the references cited therein).

### **B. Monocots**

Methods for producing transgenic plants among the monocots are currently available. Successful transformation and plant regeneration have been achieved in asparagus (*Asparagus officinalis*; Bytebier et al. (1987) *Proc. Natl. Acad. Sci. USA* 84:5345); barley (*Hordeum vulgare*; Wan and Lemaux (1994) *Plant Physiol* 104:37); maize (*Zea mays*; Gordon-Kamm et al., (1990) *Plant Cell* 2:603; Fromm et al. (1990) *Bio/Technology* 8:833; Koziel et al. (1993) *Bio/Technology* 11:194); oats (*Avena sativa*; Somers et al. (1992) *Bio/Technology* 10:1589); orchardgrass (*Dactylis glomerata*; Horn et al. (1988) *Plant Cell Rep.* 7:469); rice (*Oryza sativa*, including indica and japonica varieties; Toriyama et al. (1988) *Bio/Technology* 6:10; Zhang et al. (1988) *Plant Cell Rep.* 7:379; Luo and Wu (1988) *Plant Mol. Biol. Rep.* 6:165; Zhang and Wu (1988) *Theor. Appl. Genet.* 76:835; Christou et al. (1991) *Bio/Technology* 9:957; rye (*Secale cereale*; De la Pena et al. (1987) *Nature* 325:274); sorghum (*Sorghum bicolor*; Cassas et al. (1993) *Proc. Natl. Acad. Sci. USA* 90:11212); sugar cane (*Saccharum spp.*; Bower and Birch (1992) *Plant J.* 2:409); tall fescue (*Festuca arundinacea*; Wang et al. (1992) *Bio/Technology* 10:691); turfgrass (*Agrostis palustris*; Zhong et al. (1993) *Plant Cell Rep.* 13:1); wheat (*Triticum aestivum*; Vasil et al. (1992)

*Bio/Technology* 10:667; Troy Weeks et al. (1993) *Plant Physiol.* 102:1077; Becker et al. (1994) *Plant J.* 5:299).

### C. Expression Vectors

5 *Substantive*  
A variety of expression vectors can be used to transfer the gene encoding plant fucosyl transferase activity as well as the desired promoters and regulatory proteins into a plant. Examples include but not limited to those derived from a Ti plasmid of *Agrobacterium tumefaciens*, as well as those disclosed by Herrera-Estrella, L., et al., *Nature* **303**: 209 (1983), Bevan, M., *Nucl. Acids Res.* **12**: 8711-8721 (1984), Klee, H. J., *Bio/Technology* **3**: 637-642 (1985), and EPO Publication 10 120,516 (Schilperoort et al.) for dicotyledonous plants. Alternatively, non-Ti vectors can be used to transfer the DNA constructs of this invention into monotyledonous plants and plant cells by using free DNA delivery techniques. Such methods may involve, for example, the use of liposomes, electroporation, 15 microprojectile bombardment, silicon carbide whiskers, viruses and pollen. By using these methods transgenic plants such as wheat, rice (Christou, P., *Bio/Technology* **9**: 957-962 (1991)) and corn (Gordon-Kamm, W., *Plant Cell* **2**: 603-618 (1990)) are produced. An immature embryo can also be a good target tissue for monocots for direct DNA delivery techniques by using the particle gun 20 (Weeks, T. et al., *Plant Physiol.* **102**: 1077-1084 (1993); Vasil, V., *Bio/Technology* **10**: 667-674 (1993); Wan, Y. and Lemeaux, P., *Plant Physiol.* **104**: 37-48 (1994), and for *Agrobacterium*-mediated DNA transfer (Hiei et al., *Plant J.* **6**: 271-282 (1994); Rashid et al., *Plant Cell Rep.* **15**: 727-730 (1996); Dong, J., et al., *Mol. Breeding* **2**: 267-276 (1996); Aldemita, R. and Hodges, T., *Planta* **199**: 612-617 (1996); Ishida et al., *Nature Biotech.* **14**: 745-750 (1996)). In addition, plasmid 25 pMEN020 is described in Figure 4.

### D. Plant Regeneration

After transformation of cells or protoplasts, the choice of methods for 30 regenerating fertile plants is not particularly important. Suitable protocols are available for *Leguminosae* (alfalfa, soybean, clover, etc.), *Umbelliferae* (Carrot, celery, parsnip), *Cruciferae* (cabbage, radish, rapeseed, broccoli, etc.), *Curcubitaceae* (melons and cucumber), *Gramineae* (wheat, corn, rice, barley, millet, etc.), *Solanaceae* (potato, tomato, tobacco, peppers, etc.), and various 35 other crops See protocols described in Ammirato et al. (1984) *Handbook of Plant Cell Culture -Crop Species*. Macmillan Publ. Co. Shimamoto et al. (1989)

Nature 338:274-276;; Fromm et al. (1990) *Bio/Technology* 8:833-839. ; Vasil et al. (1990) *Bio/Technology* 8:429-434.

#### **E. Carbohydrates from Transgenic Plants**

5 Once transgenic plants are produced, carbohydrates can be isolated from the plants by procedures well known in the art. These purified carbohydrates are useful in agriculture as well medicine.

#### **F. New Complex Carbohydrates**

10 The enzymes involved in xyloglucan biosynthesis are reasonably stable and moderately abundant in plants. As such, these enzymes find use in synthesizing various types of complex carbohydrates under controlled conditions. It is also possible to make new complex carbohydrates that do not exist in Nature by procedures well known in the art.

#### **G. Carbohydrates as Herbicides**

15 *Sub B26* Fucoxyloglucan (XG) is the major hemicellulosic polysaccharide in the primary cell wall of dicots. Monocots have small quantities of XG, but it seems to be much less important in all monocots including grasses. XG has a backbone of  
20 beta-1,4 linked glucosyl residues, with three out of every four residues substituted with xylose in a regular repeat, i.e. three substituted followed by one free. Approximately one out of six of the xylosyl residues is further substituted with galactose and on the two position of galactose is an alpha linked fucosyl residue. Thus, the fucose is a peripheral sugar in this polymer.  
25 However, the fucose has been postulated to be very important in determining the conformation of the polysaccharide, including controlling interactions of XG with cellulose. Thus, the presence of fucose may be important for the function of this polysaccharide.

*Sub B27*  
30 Since XG is the major hemicellulosic polysaccharides in dicots, including many important weeds, but not very abundant in the cell walls of monocots, including corn, wheat, rice, barley, etc., inhibitors of XG synthesis may be valuable herbicides. Inhibitors include specific inhibitors of the enzyme itself and antisense constructs for inhibiting expression of the protein.

It appears that all of the enzymes that synthesize XG are part of a complex  
35 thereby permitting the use of XG-specific fucosyltransferase to identify other enzymes involved in XG synthesis. With the complete set of XG biosynthetic

enzymes in hand, rationale herbicide design is feasible by procedures well known in the art.
